Lower is better for the encoding; 0 means it hides nothing. Score: 1 = wild-type abundance, 0 = mean of nonsense variants.
lowest error any predictor reading only the encoding can reach, on these variants (95% interval: resampling positions)
error expected from replicate noise alone, if group members had equal true scores
spread of all variants (SD 0.301): error of predicting the mean for every variant
a
Groups = same encoded sequence
hp_lehninger2 (2 letters)
dayhoff6 (6 letters)
amino-acid counts only
protein20 (identity)
no two variants share this encoding
